5. Install float bowl and main mixture screw assembly. Turn screw in until lightly seated and then turn out the number of turns specified in Table 8-2.

CAUTION Forcing the mixture adjustment screws tight will damage the needle and seat. Turn in only until light tension can be felt.

6. When carburetor is installed on genset, make final adjustments to mixture screws as described in *Carburetor Mixture Screw Adjustments* (Page 8-16).

Choke Assembly

The genset has an automatic choke assembly that consists of a bimetal choke coil, coil housing (mounted on the exhaust tube) and choke linkage. The choke linkage connects to the choke shaft lever on the carburetor.

When the engine is cold, the choke coil position causes the linkage to hold the choke nearly closed. When the engine starts, hot air from the exhaust manifold enters the coil housing. The choke coil expands pulling the linkage to partially open the choke. As the engine warms up, the coil continues to expand and gradually opens the choke and holds it open while the engine is operating. This action varies the fuel/air mixture as the engine warms up to provide smooth engine operation.

If the engine starts but runs rough and exhausts black smoke after a minute or two of operation, the choke setting is too rich. If the engine starts but sputters or stops before it warms up, the choke setting is too lean.

WARNING The choke housing becomes very hot during operation and can cause severe burns if touched. Allow the genset to cool down before handling the choke assembly.

Choke Adjustment: See Figure 8-23. Check the choke linkage to make sure it is not bent or rubbing. Rotate the choke lever on the carburetor. The choke shaft should move freely and it should return to its original position when released. To readjust the choke:

1. Let the genset cool down (overnight) in an ambient of 60-80° F (15-27° C).
2. Loosen the two choke adjustment plate lock screws.
